

**Question 2: It is said that an object "knows stuff" and can "do stuff". Explain what this means in the context of object-oriented programming.**

In the context of object-oriented programming, this means that the object has methods and properties that can interact with other objects, turning programming from a language into a game, where you can build programs with blocks instead of syntax.

**Question 3: Why is an object's internal data to be "hidden" from outside code? What is the technical term for this principle of good design?**

An object's internal data should be hidden from outside code to prevent the object from being corrupted. The technical term is called Encapsulation, which compacts attributes and methods into a class. This prevents access to the inner methods, which grants the program security and defense against users trying to modify the program (used a lot in video games, as you could just change an attribute to give yourself infinite money otherwise).
