

Question 2: Which is more specialized, the superclass or the subclass? Explain.

The subclass is more specialized, and the superclass is more general. This is because subclasses inherit common traits from their parents, but also add more specific attributes or methods, which make them more precise than the parent class.

Question 3: What does it mean to say there is an "is a" relationship between two classes?

This means that one class is a specialized version of another class, which inherits the other class' methods and attributes. This means that the child class can do everything the parent class can, but with more functionality.

Question 4: What does a subclass inherit from its superclass?

A subclass inherits all methods and attributes that are public from the superclass, allowing the subclass to reuse code, variables and methods from the parent, while also allowing it to add new functionality or override existing methods.
