

Question 2: What is an overridden method? Explain why overriding a method inherited from a superclass can be useful.

An overridden method is a method that is allowing the subclass to create a specific implementation of a method that is already defined within the superclass. This is quite literally what Polymorphism is, where the subclass version of the method runs based on the object's type. This can be useful as you can make different class behaviors specific, for example when a dog speaks it barks, whereas the cat decides to meow.

Question 3: The following code is saved in a file called veggies.py. Without executing the code, determine what the output will be. Run the code with the Python interpreter to verify.

Assuming the code is fixed (as right now there are no brackets around the strings after the print statements), the code will likely first print out "I'm a potato." and then "I'm a vegetable." After running the code with the Python interpreter, I can confirm that my conclusion was correct and the expected output was displayed.
