

Question 1: You want the user to select only one item from a group. Which component would you use for the items: radio buttons or checkboxes?

Radio buttons are a better choice if you want the user to select only one item from a group. This is because radio buttons only allow for one answer, whilst multiple checkboxes can be checked, resulting in multiple answers.

Question 2: You want the user to be able to select any number of items from a group. Which type of component would you use for the item: radio buttons or check boxes?

Check boxes are a better choice if you want the user to select multiple items from a group. This is because checkboxes allow for multiple answers, whilst only one radio button can be checked, resulting in only one answer.

Question 3: How can you use an IntVar object to identify which RadioButton has been chosen in a group of RadioButtons?

You can use an IntVar object to identify which RadioButton has been chosen in a group of RadioButtons by assigning each radio button a unique integer value. When one of the buttons is selected, it will store a specific integer value in the IntVar object. You can then use that integer value to determine which option was picked.

Question 4: How can you use an IntVar object to check if a Checkbutton is selected?

Unlike the radio buttons, each Checkbutton is associated with a different IntVar object. When the user selects a check box, the IntVar will have a value of one. When deselected, the IntVar holds a value of zero. You can then check which IntVars have a value of one to determine which Checkbuttons the user has selected.
